

Q3. Can you explain what a stream is in programming and give a simple example of how it is used?

SCORE: 55%

CANDIDATE ANSWER

A **stream** processes data **piece by piece** instead of loading everything at once. For example, reading a large file line-by-line using a file stream instead of loading the entire file into memory.

Q4. Can you discuss how streams handle backpressure and how it impacts data flow?

SCORE: 49%

CANDIDATE ANSWER

Backpressure occurs when a data consumer is slower than the producer; streams handle it by slowing or pausing the producer until the consumer is ready, preventing memory overload and maintaining smooth data flow.

Q5. What is a module in programming, and why is it used?

SCORE: 49%

CANDIDATE ANSWER

A **module** is a self-contained piece of code that groups related functionality, making programs **organized, reusable, and easier to maintain**.

Q6. Can you explain how module imports and exports work in your preferred programming language?

SCORE: 55%

CANDIDATE ANSWER

In JavaScript, you use `export` to make functions/variables available and `import` to use them in another module. `// math.js export const add = (a, b) => a + b; // app.js import { add } from './math.js';` So, `export` shares code; `import` brings it into another file.

Q7. Can you define what middleware is and explain its role in software architecture?

SCORE: 49%

CANDIDATE ANSWER

Middleware is a software layer between application components that processes requests, data, or responses, handling tasks like authentication, logging, validation, and error handling.

Q8. Can you provide an example of a specific middleware pattern used in web applications and explain how it functions within that

SCORE: 49%
